

Offgrid

Your medical history lives on your phone.
Hospitals see only what you approve.

Health data is scattered, and patients have no say

Same forms, every hospital

Patients repeat their details everywhere, and their history is split across hospitals.

No visibility

Patients cannot see or control who looked at their records.

Fake looks real

A photo of a lab report looks the same as a doctor-verified record.

Emergencies

An unconscious patient cannot approve anything, yet staff need critical facts.

The patient approves every share

Show a QR

One-time code, no
medical data inside

Hospital scans

It sees name and age
only

Hospital asks

Specific records,
from a named
hospital

Patient decides

Approve, narrow or
deny, with a time
limit

Approved only

Everything else stays
hidden

Revoke any time, even a single doctor. Every access is logged.

Doctor-signed records stand apart from uploads

Verified

A doctor reviewed and signed it. Source, author and date are shown.

Unverified

Uploaded or added, not yet signed. Never mixed into verified history.

Tamper alarm

Change a signed record and the signature check fails, so the app warns.

Records signed with Ed25519, shown to the hospital

A doctor visit, start to finish

1 Reception assigns an available doctor

2 Doctor scans the patient's QR on arrival

Security is built in, not bolted on

Consent on every read

Valid, unexpired, unrevoked, right category, right hospital.

Doctor signatures

Ed25519 over the record and its files.

Signed means locked

A database rule blocks edits and deletes.

Audit log

Append-only, with scrambled patient references.

Encrypted notes

AES-256-GCM at rest, bcrypt passwords.

Emergency, limited

Critical facts only, one hour, patient notified.

Tested, and honest about limits

90

automated
checks pass

0

real patient
records used

Fresh

clone verified
from GitHub

- Threat model and test cases are in the repo
- End-to-end test covers consent, signing, revoke, visits
- Synthetic data only, local environment

What production still needs

- Doctor keys in an HSM, not the database
- Password reset by email code, not birth date
- NFC cards and verified hospital onboarding
- Encrypted file storage, TLS, regulatory review

Patient approves. Doctor signs. Everything is logged.
